Abstract—Computational quantum chemistry mehods such as the Hartree-Fock (HF), the density functional theory (DFT) or the fragment molecular orbital (FMO) require heavy computational resources. In this study they are accelerated by using graphics processing units (GPUs) and the vector instruction set (AVX) of latest CPU. PRISM algorithm to evaluate the electron repulsion integrals was vectorized to utilize AVX as much as possible. We found that this new program makes the Fock matrix formation in HF 2 to 3 times faster than ever before. The Coulomb and the exchange-correlation potentials in DFT were evalualted on GPU, result in about 4 times overall speedup. The programs developed were used to accrelerate FMO. We found that our new algorithm and GPU are very suitable for the calculation of the environmental electrostatic potential. The total computational time was reduced to about 1/3.

# Abstract

Benchmark : multicore CPUs

- Vectorized PRISM by AVX on Sandybridge CPU
  - HF (Hartree-Fock) : x 3 faster
- DFT by CUDA on NVIDIA GPU
  - J-matrix formation : x 245
  - Exchange correlation : x 4

NVIDIA GPU

- ERI J-matrix (Coulomb potential) by CUDA on NVIDIA GPU
  - FMO Environmental Electrostatic Potential : x 17

Replace HF, DFT, FMO ESP with CUDA/AVX scratch code

Acceleration so much

GAMESS-US + XA-AVX/CUDA-QM

### CPU[AVX]/GPU[CUDA] hybrid programming

- No GPU Program run without CPUs.
   CPU+GPU architecture is general.
- SSE/AVX should be appropriate if the process is suitable for SIMD parallelization and not for GPU.
  - AVX computes 4 double precision arithmetics at once.
  - AVX is theoretically twice faster than SSE.
  - <u>AVX is available on latest CPU (SandyBridge).</u>
    - A normal Desktop PC is used in this research.

# AVX : Pros and Cons

Basically, it is like a vector processor.

Pros	Cons
<ul> <li>Twice faster than SSE</li> <li>SIMD parallelization</li> <li>utilizes main memory same as FPU computing</li> </ul>	<ul> <li>Poor for algorithms that use conditional branching and/or random memory access</li> <li>Automatic vectorization is efficient only for simple cases</li> </ul>

### Plan for implementation

AVX	GPU
<ul> <li>Define overloaded operators of C++ to avoid using AVX intrinsic functions explicitly.</li> </ul>	<ul> <li>Use best tuned algorithm as far as GPU's resource permits.</li> <li>Shared memory of Fermi core is used as L1 cache.</li> <li>Use CPU threads (pthread) to harness GPU calculations for</li> </ul>
<ul> <li>Use function pointers of C/C++ to eliminate branches in most inner loop.</li> </ul>	<ul> <li>complicated thread control (synchronization, queueing).</li> <li>Use OpenMP for CPU thread parallelization.</li> <li>Single/double mixed-precision calculation.</li> </ul>

# System Configuration

- Core i5 2500 @ 3.30GHz
- NVIDIA Geforce GTX580
  - 512 cuda cores
- DDR3 8GB
- CUDA 4.0
- Intel Composer XE 2011

### How to solve Schrödinger equation? $H(1\cdots N)\Psi(1\cdots N) = E\Psi(1\cdots N)$ Expand wave function with "contracted Gaussian basis set" (Linear Combination of Atomic Orbital S approximation) $\psi_i(r) = \sum C_k^{(i)} \chi_k(r)$ $s: \chi(r) = \sum_{k=1}^{K} d_k e^{-\alpha_k (r-A)^2} \quad p_x: \chi(r) = \sum_{k=1}^{K} d_k (x - A_x) e^{-\alpha_k (r-A)^2}$

 $F(C)C = SC\mathcal{E}$  Matrix form of eigenvalue problem (Self consistent)

Copyright (C) 2011 X-Ability Co., Ltd.

### Summary of Hartree-Fock Procedure

$$F(C)C = SC\varepsilon : SCF \qquad (ab | cd) = \int \frac{\chi_a(r)\chi_b(r)\chi_c(r')\chi_d(r')}{|r-r'|} dr' dr : ERI$$

$$F_{\mu\nu} = H_{\mu\nu}^{core} + \sum_{a}^{2/N} \sum_{\lambda\sigma} C_{\lambda a} C_{\sigma a}^* \left[ 2(\mu\nu|\sigma\lambda) - (\mu\lambda|\sigma\nu) \right]$$

$$= H_{\mu\nu}^{core} + \sum_{\lambda\sigma} D_{\lambda\sigma} \left[ (\mu\nu|\sigma\lambda) - \frac{1}{2}(\mu\lambda|\sigma\nu) \right]$$

$$= H_{\mu\nu}^{core} + G_{\mu\nu}$$

**Density Matrix (D)** : is updated at every SCF cycle to solve nonlinear equation after initial guess.

**ERIs (ab|cd) :** may be calculated only once and store them on memory in principle, but it needs large O(N<sup>4</sup>) memory. They are recalculated at every cycle (direct SCF) to reduce expensive disk I/Os. <u>This step is bottleneck.</u>

**Density Matrix** × **ERI** = **J-matrix** : Coulomb potential matrix

**Density Matrix** × **ERI** = **K-matrix** : HF exchange matrix. GPU implementation is not easy because it needs a lot of registers.

#### Hermite Gaussian Basis Set

$$[p] = H_t (x - P_x) e^{-\varsigma (x - P_x)^2} \times (y \text{ factor }) \times (z \text{ factor })$$
  
**t-th Hermite polynomial**

A Product of two Gaussian functions [ab] is expanded exactly by Hermite Gaussians [p].

ERI calculation in Hermite Gaussians space is faster than that in the normal Gaussians. Because of the communication cost we can't get each ERI [p|q] from GPU.

Copyright (C) 2011 X-Ability Co.,Ltd.

# Procedure of J-matrix (Coulomb)

Less than 10% of total cost

### **Density Functional Theory (DFT)**

Hartree-Fock : 
$$F_{\mu\nu} = H^{core}_{\mu\nu} + J_{\mu\nu} + K_{\mu\nu}$$
  
DFT :  $F_{\mu\nu} = H^{core}_{\mu\nu} + J_{\mu\nu} + v_{\mu\nu}$ 

Exchange correlation  $v_{kl} = \int \chi_k(r) \chi_l(r) f(\rho(r), \nabla \rho(r)) dr$ 

Acceleration of J-matrix + Exchange Correlation is necessary.

# original GAMESS J-matrix is very slow because ERIs are explicitly calculated in Cartesian Gaussian basis.

# PRISM implementation (1) [AVX]

- PRISM Algorithm
  - ✓ One of the fastest algorithms to evaluate ERIs.
  - ✓ adopted by Gaussian (famous QM software)
  - ✓ Constantly fast for various contraction length / angular momentum.
  - ✓ Convert Boys function [0]<sup>(m)</sup> ∝ ∫u^m exp(-Tu)du to ERI using recurrence with a guide of "PATH". Chooses the best path for different contraction length / angular momentum.

# PRISM implementation (2) [AVX]

Figure 2. The general PRISM from  $[0]^{(m)}$  to (bra | ket).

#### Gill and Pople(1991)

All recurrence formulae are

(Integral A) = a \* (Integral B) + b \* (Integral C)

The same recurrence formula is applied to the intermediate integrals of the same shell type (angular momentum, bra/ket contraction length). It would be suitable for SIMD parallelization.

# PRISM implementation (3) [AVX]

class double4

# operator overload

public:

```
double4& operator=(double d){
  m_d = _mm256_set1_pd(d);
```

return \*this;

```
}
double4 operator+(const double4& dd){
```

```
return double4(_mm256_add_pd( m_d, dd.m_d) );
```

```
}
// ... define other operators
___m256d m_d;
```

#### Difference between PRISM of ours and Gaussian 's

 $\mathbf{X} \xrightarrow{\text{Ability}}_{2 \square \exists \mathcal{T} \not\models \forall \neg \neg \forall \forall \neq \forall}$ 

	Gaussian	X-Ability
What is it	classifies shell quartets $(ab   cd)$ by shell type and number of bra/ket contraction so that "Driver" is determined on each shell quartet on the fly.	generates source code of all PRISM paths and sets appropriate <b>function</b> <b>pointer</b> for each calculation target dynamically.
Pros	A recurrence formula is applied to long-enough batch of shell quartets so that it is suitable for traditional vector processors.	Only 4 shell quartets are processed at once, resulting to avoid cache misses.
Cons	Not suitable for scalar processors because it might results in cash misses. A compiler could not optimize the program efficiently.	The code has tens of thousands lines and 300-400MB volume.

#### Calculation Result of Hartree-Fock [AVX]

10<sup>-7</sup>hartree is enough accuracy. We replaced GAMESS ERI with XA PRISM.

### Test Model

### Insulin (PDBID:2HIU)

44 amino acids

### Acceleration of Environmental Electrostatic Potential (ESP)

- Utilize ERI J-matrix  $J_{ab} = \sum_{cd} (a + basis on neighboring fragments)$
- Decompose protein into many small fragments such as amino acid molecules.

Conventional SCF (ERIs saved on disk) is effective for usual amino acids (# of basis < 180).

ERI is not bottleneck in FMO.

**Environmental electrostatic potential dominates.** 

• Utilize J-matrix acceleration program by

# Total Energy of Insulin

	Time [sec]	Total Energy [a.u.]
<b>Original GAMESS</b>	14158.0	-21635.4488653044
Our work	3807.5	-21635.4488649218

- Error of total energy of 44 fragments is small enough.
- Energy of each amino acid is highly consistent.

# FMO ESP[GPU] and SCF[AVX] calculation time of Insulin

	GAMESS	This work	speedup
ESP part(GPU)	10696.2	640.0	x 16.71
SCF part(AVX)	2475.1	2136.8	x 1.16
Total	14158.0	3807.5	x 3.72

ESP part is much better than total acceleration ratio.

#### Summary of performance results & discussion

	AVX	GPU
Summary of performanc e results	Hartree-Fock x 3 by Vectorized PRISM	DFT J-matrix formation: x 245 Exchange correlations: x 4 FMO ESP : x 17
Discussion	Unpredictable implementation cost	Difficulty of simple parallelization by register shortage. Few cost of the transfer speed between host and device using contracted Gaussian basis set.

#### **GPGPU** is better regarding price performance ratio.

## Further acceleration and improvement

• HF [AVX]

Improvement of evaluation part of Boys function  $[0]^{\left(m\right)}$ 

• DFT [GPU]

Grid generation of DFT

• FMO [AVX+GPU]

HF acceleration by AVX brings FMO acceleration, and investigate extra overhead time.

Others, technically speaking
 OpenCL, cluster tuning by hardware, etc.

# Thank you for your attention.
